1. Executive Summary

In March and April 2016 a collaborative study was conducted between national scientists with expertise in Japanese, Taiwanese, and Korean longline fleets, and an independent scientist. The meetings addressed Terms of Reference covering several important issues related to albacore, bigeye and yellowfin tuna CPUE indices in the Indian Ocean. A further meeting between the parties was held in July 2016 to update the tropical tuna indices. The study was funded by the International Seafood Sustainability Foundation (ISSF) and the Indian Ocean Tuna Commission (IOTC).

Terms of Reference:

- 1. To validate and improve methods for developing indices of abundance for tropical tunas.
- 2. To develop methods for providing indices of abundance for albacore tuna.
- 3. To provide indices of abundance for albacore tuna, and to draft a working paper to be presented at the 2016 WPTmT06 (18 21 July 2016).
- 4. To provide indices of abundance for bigeye and yellowfin tunas and to draft a working paper to be presented at the WPTT18 (5 10 November 2016).
- 5. To provide support and training to national scientists in their analyses of catch and effort data.

This document describes the development of indices of abundance for albacore tunas.

Data were provided for the three fleets in similar formats, with varying combinations of species and variables, due to differences between the fisheries' data collection forms and processes and their changes through time. See Table 9 for a comparison of field availabilities among the three fleets. All datasets reported set date, number of hooks, hooks between floats for at least part of the time series, set location at some resolution, vessel identity for part or all of the dataset, and catch in number of albacore, bigeye, yellowfin, southern bluefin tuna, swordfish, blue marlin, striped marlin, and black marlin.

Japanese operational data were available from 1952-2015, with location reported to 1° of latitude and longitude, vessel call sign from 1979, hooks between floats for much of the time series, and date of trip start (Tables Table 2 and Table 3). The Taiwanese operational data were available 1979-2015, but data prior to 2005 were not used in tropical tuna analyses, due to concerns about data quality. Taiwanese vessel call sign was available for the whole time period along with information on vessel size; set location at 5° resolution until 1994, and 1° subsequently; number of hooks between floats from 1995; and catches in number for the species above plus other tuna, other billfish, skipjack, shark, and other species; equivalent values in weight for all species; SST; bait type fields ('Pacific saury', 'mackerel', 'squid', 'milkfish', and 'other'); depth of hooks (m); set type (type of target); remarks (indicating outliers); departure date from port; starting date of operations on a trip; stopping date of operations on a trip; and arrival date at port (Table 4). Korean data were available for 1971 to 2015 (Table 8), with the standard fields and vessel id, operation location to 1°, hooks between floats calculated for each set, and additional species 'other', sailfish, shark, and skipjack. All operational data was available only for the purpose of this collaborating work. No operational data is available after this collaborating work.

Data were cleaned by removing obvious errors and missing values (Figure 5). Unlikely but potentially plausible values (e.g. sets with very large catches of a species) were retained. Each set was allocated to albacore regions according to several alternative regional

definitions, and data outside these areas ignored. Standard datasets were produced for each fleet.

We applied cluster analysis methods to identify effort associated with different fishing strategies, using the approaches developed in the 2015 IOTC CPUE standardization workshop (Hoyle *et al.* 2015). Data were aggregated by vessel-month and then clustered on species composition in the catch, using the Ward hclust method. Clustering was carried out by fleet and region, and a fleet/cluster group parameter was assigned to each set. The clustered data for all fleets in a region were combined into a joint dataset. For each region and fleet, clusters were removed if the species of interest was a very small component of the catch.

Data for each region were standardized using regression techniques to estimate indices of abundance. The dependent variable was the presence/absence of the species of interest in the catch (binomial models), or the positive catch of the species of interest in numbers of fish (lognormal models). All models included the explanatory variables year-quarter and 5° cell as categorical variables, a cubic spline on hooks as a covariate, and a categorical variable for cluster. Some models were run with vessel identity as a categorical variable. Models were run for the period 1952-1979 without vessel identity, for the later period 1979-2015 with vessel identity, and for the whole period 1952-2015 both with and without vessel identity. Indices were estimated using both a delta lognormal approach, and lognormal constant generalized linear models.

Figures and tables are provided for each set of indices, including both quarterly and annual indices. Diagnostic plots are also presented.

2. Introduction

In March and April 2016 a collaborative study of longline data and CPUE standardization for bigeye, yellowfin, and albacore tuna was conducted between scientists with expertise in Japanese, Taiwanese, and Korean fleets, and an independent scientist. A further meeting was held in July 2016 to update the tropical tuna analyses with the most recent data. The study was funded by the International Seafood Sustainability Foundation (ISSF) and the Indian Ocean Tuna Commission (IOTC). The study addressed the Terms of Reference outlined below, which cover the most important issues that had previously been highlighted by different working parties. Work was carried out, for those factors relevant to them, for the following:

· Area: Indian Ocean

• Fleets: Japanese longline; Taiwanese longline, Korean longline

• Stocks: Bigeye tuna, yellowfin tuna, albacore tuna.

The current document addresses CPUE standardizations for albacore tuna. The methods description includes approaches used for bigeye, yellowfin, and albacore tunas in order to generalize the report, but to conserve space only albacore tuna results are reported.

2.1. Terms of Reference

- To organize a series of meetings between data holders and the consultant.
- To validate and improve methods for developing indices of abundance for tropical tunas.
- To develop methods for providing indices of abundance for albacore tuna.
- To provide indices of abundance for albacore tuna, and to draft a working paper to be presented at the 2016 IOTC WPTmT06 (18 21 July 2016).
- To provide indices of abundance for bigeye and yellowfin tunas and to draft a working paper to be presented at the IOTC WPTT18 (5 10 November 2016).
- To provide support and training to national scientists in their analyses of catch and effort data.
- The analyses will consider data to be provided by Japanese, Taiwanese, and Korean research agencies.
- Analyses will be carried out in a series of meetings in March and April, and in a final meeting focusing on tropical tunas following update of the data. After preliminary meetings between the consultant and each participating data provider to prepare each dataset and develop methods, there will be a first joint meeting between all participating parties and the consultant. This joint meeting will develop indices for albacore tuna and develop draft indices for bigeye and yellowfin tunas. A second joint meeting will occur in July or August to prepare final indices for bigeye and yellowfin tuna, and to provide training to national scientists in their analyses of catch and effort data.

• Data analysis tasks will include the following:

Load, prepare, and check each dataset, given that data formats and pre-processing
often change between years and data extracts, and important changes to fleets and
reporting sometimes occur in new data. The format of the Japanese data is expected
to change before the second joint meeting which will require additional time during
this meeting.

- Explore albacore catch and effort data from each CPC to check the reliability and coverage of reporting, as we did for tropical tunas
- Apply cluster analyses and BET + YFT CPUE standardization using reliable data from each CPC. Change regional structures from the generic 2015 approach to regions that are appropriate for each assessment, including alternate options.
- Address outstanding issues from 2015 tropical tuna analyses, including a) adjusting for the introduction of vessel effects in late-1970s Japanese data, and b) producing joint indices for temperate areas.
- Add functionality to provide estimates of relative observation error (CIs) by time period.
- Extend the approach to albacore standardization, i.e. cluster analyses and CPUE standardization with appropriate spatial structures.
- Thoroughly check all code and results in order to validate indices.

•

- All work is subject to the agreement of the respective fisheries agencies to make the data available.
- To document the analyses in accordance with the IOTC "Guidelines for the presentation of CPUE standardisations and stock assessment models", adopted by the IOTC Scientific Committee in 2014; and to provide draft reports to the IOTC Secretariat no later than 60 days prior to the meetings of the WPTmT06, i.e. 18 May 2016, and WPTT18, i.e. 6 September 2016, and the final report no later than 15 days prior to the meeting of the WPTT18, i.e. 21 October 2016.
- To undertake any additional analyses deemed relevant by the WPTT18 or the IOTC Secretariat up to 60 days after the start date of the contract.

3. Methods

3.1. Data cleaning and preparation

The three datasets had many similarities but also significant differences. The variables differed somewhat among datasets, as did other aspects such as the sample sizes, the data coverage and the natures of the fleets.

Data preparation and analyses were carried out using R version 3.3.0 (R Core Team 2016).

The approaches used here are based on those applied by Hoyle *et al.* (2015), with modifications where required. For more detail about the Japanese, Korean, and Taiwanese fleets, see the descriptive figures in the following papers (Hoyle *et al.* 2015, Hoyle *et al.* 2015)

3.1.1. Data

In this section we describe the datasets provided by Japanese, Taiwanese, and Korean data managers, and the methods that we used to prepare and clean the data for analysis. As the provided datasets were prepared for this collaborative study, the data do not include all information potentially included in logbook data. The cleaning described here differs from the standard cleaning procedures by national scientists when producing CPUE indices. All operational data were available only for the purpose of this collaborating work. No operational data is available after this collaborating work.

Japanese data were available from 1952-2015 (Figure 2), with fields year, month and day of operation, location to 1° of latitude and longitude, vessel call sign, no. of hooks

between floats, number of hooks per set, date of the start of the fishing cruise, and catch in number of southern bluefin tuna, albacore, bigeye, yellowfin, swordfish, striped marlin, blue marlin, and black marlin.

The Taiwanese operational data were available 1979-2015 (Figure 3), but data prior to 2005 were not used in tropical tuna analyses, due to concerns about data quality applying to bigeye tuna in particular (see details in Hoyle *et al.* (2015)). Available fields were year, month and day of operation; vessel call sign; operational area (a code indicating fishing location at 5° resolution); operation location at 1° resolution (from 1994); number of hooks between floats (from 1995); number of hooks per set; catches in number for the species albacore, bigeye, yellowfin, bluefin (from 1993), southern bluefin (from 1994), other tuna, swordfish, striped marlin, blue marlin, black marlin, other billfish, skipjack, shark, and other species; equivalent values in weight for all species; SST; bait type fields for 'Pacific saury', 'mackerel', 'squid', 'milkfish', and 'other'; depth of hooks (m); set type (type of target, from 2006); remarks (indicating outliers); departure date from port; starting date of operations on a trip; stopping date of operations on a trip; arrival date at port (Table 4).

Korean operational data were available for 1971 to 2015 (Table 8, Figure 4), with fields vessel id, operation date, operation location to 1°, number of hooks, number of floats, and catch by species in number for albacore, bigeye, black marlin, blue marlin, striped marlin, other species, southern bluefin, sailfish, shark, skipjack, swordfish, and yellowfin.

The contents and preparation of logbook data is described below for each variable. See Table 9 for a comparison of field availability among the three fleets.

In the Japanese data international call sign was available 1979 - present, and was selected as the vessel identifier. Call sign is unique to the vessel and held throughout the vessel's working life. In the Taiwanese data, the international call sign was available for each set, and was also selected as the vessel identifier. The first digit of the Taiwanese callsign indicated the tonnage of the vessel (Table 5). In the Korean data the callsigns were understood to have changed through time to some extent, and so vessel ids were assigned based on a combination of vessel names and vessel callsigns. For all fleets, the vessel id was rendered anonymous by changing it to an arbitrary integer. Sets without a vessel call sign were allocated a vessel id of '1'. For joint analyses, a fleet code was added to differentiate vessels from different fleets.

In all Japanese and Korean data, and in most Taiwanese data from 1994, latitude and longitude were reported at 1° resolution, with a code to indicate north or south, west or east. Taiwanese fishing locations were otherwise reported at 5° square resolution using a logbook code. All data were adjusted to represent the south-western corner of the $1 \times 1^\circ$ square, and longitudes translated into 360° format. Each set was allocated to regions according to various alternative region definitions, including 2 definitions for yellowfin (Langley 2015), 3 for bigeye (Langley *et al.* 2013), and 6 for albacore. Data outside these areas were ignored. Location information was used to calculate the 5° square (latitude and longitude).

Hooks per set were reported in all datasets, and the few sets without hooks were deleted. For the purposes of further analyses, we cleaned the data by removing data likely to be in error. The criteria were selected after discussion with experts in the respective datasets. In the Japanese and Korean data, hooks per set above 5000 and less than 200 were removed. In the Taiwanese data hooks per set over 4500 and less than 200 were removed. The difference between fleets was unintentional, but there were very few sets with 4500-5000 sets, so there was little or no impact on results. A very high proportion of

Taiwanese sets reported 3000 hooks per set, to an increasing degree through time. This difference from the other fleets and remarkable uniformity may be genuine, or may indicate a reporting problem, and warrants further investigation.

The three fleets all reported catch by species in numbers, but for slightly different species. The Japanese reported bigeye, yellowfin, albacore, southern bluefin tuna, swordfish, striped marlin, blue marlin, black marlin. The Taiwanese reported all these but included fields for skipjack, bluefin, sharks, other tunas, other billfish, and other species. The Taiwanese also reported catch by species in weight, but we used only the number information. Korea reported the same species as Japan and also skipjack, sailfish, sharks, and other species. The sailfish category may include shortbill spearfish (Uozumi 1999).

In the Taiwanese logbook, columns for bluefin and southern bluefin tuna were added in 1994. Prior to this bluefin were only recorded in the database when individuals changed the heading in the logbook. The number of reported bluefin increased substantially in 1994. We reassigned any fish reported as bluefin to the southern bluefin tuna category. The field labelled 'white marlin' represents striped marlin in the Indian Ocean. With the three fields for 'other' species, 'other tunas' are thought to be mostly neritic tunas, 'other billfish' may represent mostly sailfish and possibly shortbill spearfish, and 'other fish' particularly in recent years mostly oilfish.

In the logbooks of each fleet some very large catches were reported at times for individual species, but were not removed since there was anecdotal evidence that they may be genuine, and because they are unlikely to affect results substantially. Further investigation should consider the pros and cons of retaining these values.

In the Japanese logbook hooks between floats (HBF) were available for almost all sets 1971-2015 (Table 3), and for a high proportion of sets 1958-1966. Sets after 1975 with HBF missing or > 25 were removed. Sets before 1975 with missing HBF were allocated HBF of 5, according to standard practice with Japanese longline data (e.g. Langley *et al.* 2005, Hoyle *et al.* 2013, Ochi *et al.* 2014). In the Taiwanese logbook hooks between floats (HBF) were available from 1995. In the Korean logbook HBF was not available but the number of floats was reported, so we calculated HBF by dividing the number of hooks by the number of floats and rounding it to a whole number.

The remarks section of the Taiwanese dataset indicated outliers and other anomalies. Codes and criteria for outliers changed in 2012. Before 2012 an outlier was flagged if there was catch of more than 5 tons of a species per set, or outliers in the distribution of species catch number per set. From 2012 an outlier was flagged according to the 'IQR rule'. 1. Arrange average catch numbers per set (within a year) for all vessels in order. 2. Calculate first quartile (Q1), third quartile (Q3) and the interquartile range (IQR=Q3-Q1). 3. Compute Q1-1.5 x IQR and Compute Q3+1.5 x IQR. Anything outside this range is an outlier. This outlier information is used in the standard data cleaning procedures for Taiwanese standardisations. We did not use the outlier information in data cleaning for this paper.

After data cleaning, a standard dataset was produced for each fleet to be used in subsequent analyses (Figure 5).

Each set was allocated to bigeye, yellowfin, and albacore regions. These regions are based on the region definitions used in the stock assessments for each species. Several regional structures were explored for each species, but here we present six options for albacore (Figure 1). Data outside these regions were ignored. Subsequent analyses were performed separately for each region in each regional structure.

3.2. Cluster analysis

Bigeye and yellowfin comprise a large proportion of the catch north of about 15° S, and a lower proportion further south (Figure Figure 6). This pattern applied across all fleets, but there were also spatial and temporal differences in species composition patterns among fleets. The Taiwanese fishery included an oilfish fishery which developed from about 2005 in the southwest Indian Ocean (Figure Figure 7).

We clustered the data using the approach applied by Hoyle *et al.* (2015). We removed all sets with no catch of any of the species, and then aggregated by vessel-month. Set level data contains variability in species composition due to the randomness of chance encounters between fishing gear and schools of fish. This variability leads to some misallocation of sets using different fishing strategies. Aggregating the data tends to reduce the variability, and therefore reduce misallocation of sets. For these analyses we aggregated the data by vessel-month, assuming that individual vessels tend to follow a consistent fishing strategy through time. One trade-off with aggregation in this way is that vessels may change their fishing strategy within a month, which will result in misallocation of sets. For the purposes of this paper we refer to aggregation by vesselmonth as trip-level aggregation, although the time scale is (for distant water vessels) in most cases shorter than a fishing trip. For Japanese data prior to 1979 vessel id was not available, but we were able to cluster them by vessel-month because the logbook id, available for the first time in the current data set, could be used to identify sets on the same vessel-trip.

We calculated proportional species composition by dividing the catch in numbers of each species by catch in numbers of all species in the vessel-month. Thus the species composition values of each vessel-month summed to 1, ensuring that large catches and small catches were given equivalent weight. The data were transformed by centring and scaling, so as to reduce the dominance of species with higher average catches. Centring was performed by subtracting the column (species) mean from each column, and scaling was performed by dividing the centred columns by their standard deviations.

We clustered the data using the hierarchical Ward hclust method, implemented with function hclust in R, option 'Ward.D', after generating a Euclidean dissimilarity structure with function 'dist'. This approach differs from the standard Ward D method which can be implemented by either taking the square of the dissimilarity matrix or using method 'ward.D2' (Murtagh and Legendre 2014). However in practice the method gives similar patterns of clusters to other methods, more reliably than ward.D2 (Hoyle et al 2015).

Data were also clustered using the kmeans method, which minimises the sum of squares from points to the cluster centres, using the algorithm of Hartigan and Wong (1979). It was implemented using function kmeans in the R stats package (R Core Team 2014).

3.2.1. Selecting the number of groups

We used several subjective approaches to select the appropriate number of clusters. In most cases the approaches suggested the same or similar numbers of groups. First, we applied hclust to transformed trip-level data and examined the hierarchical trees, subjectively estimating the number of distinct branches. Second, we ran kmeans analyses on untransformed trip-level data with number of groups k ranging from 2 to 25, and plotted the deviance against k. The optimal group number was the lowest value of k after which the rate of decline of deviance became slower and smoother. Third, following Winker et al (2014) we applied the nScree() function from the R nFactors package (Raiche and Magis 2010), which uses various approaches (Scree test, Kaiser rule, parallel analysis, optimal coordinates, acceleration factor) to estimate the number of components

to retain in an exploratory PCA. Where there was uncertainty about the number of clusters, we selected the option with more clusters.

3.2.2. Plotting and data selection

We plotted the hclust clusters to explore the relationships between them and the species composition and other variables, such as HBF, number of hooks, year, and set location. Plots included boxplots of a) proportion of each species in the catch, by cluster; b) the distributions of variables by cluster; and c) maps of the spatial distribution of clusters, one map for each cluster.

In some analyses clusters that caught very few of the species of interest were omitted, because they provide little relevant information and may cause analysis problems due to large numbers of zeroes, and memory problems due to large sample sizes. Cluster selection was based on review and discussion of the plots of covariates and species compositions by cluster. Analyses were run both with and without these clusters – see the 'Models and datasets' section.

We pooled data from multiple fleets into a single analysis for years 1952-2015. The pooled dataset included all data from the Japanese (1952-2015) and Korean (1971-2015) fleets. For the Taiwanese fleet 1979-2015 were included for albacore, and 2005-2015 for tropical tunas.

For standardization of each region, data were selected for vessels that had fished for at least N1 quarters in that region. The standard level of N1 was 8 quarters in the equatorial regions and 2 quarters in the southern regions. Subsequently, vessels, 5° cells, and year-quarters were included if they had at least 100 sets. For analyses of the 1952-1979 period this criterion was reduced to 50 sets, to increase the size of the dataset. For datasets with more than 60,000 sets the number of sets in each stratum (5° square * year-quarter) was limited by randomly selecting 60 sets without replacement from strata with more than this number of sets. Testing suggested that this approach did not cause bias, and the effects on trends of random variation were reduced to very low levels at 30 sets per stratum (Hoyle and Okamoto 2011, Hoyle and Okamoto 2011), suggesting that 60 sets was more than adequate.

- 3.3. CPUE standardization, and fleet efficiency analyses CPUE standardization methods generally followed the approaches used by Hoyle and Okamoto (2011) with some modifications. The operational data were standardized using generalized linear models in R. A large number of analyses were carried out.
- 1. Analyses were carried out for each species.
- 2. Initially analyses were carried out for multiple regional structures, though this was later reduced to one each for bigeye and yellowfin, and two for albacore.
- 3. Analyses for bigeye and yellowfin were conducted using five alternative models and datasets, described below, while analyses for albacore were conducted using one model and dataset.
- 4. Separate analyses were run for each region, ranging from one to four regions per structure.
- 5. Up to three modelling distributions were used: lognormal constant, delta lognormal, and negative binomial. Lognormal constant was used for all species, delta lognormal for bigeye and yellowfin, and negative binomial for albacore.
- 6. Analyses were run for four alternative data groups, as described below.

3.3.1. Distributions

Lognormal constant analyses were carried out using generalized linear models that assumed a lognormal distribution. In this approach the response variable

 $\log{(CPUE+k)}$ was used, and a Normal distribution assumed. The constant k, added to allow for modelling sets with zero catches of the species of interest, was 10% of the mean CPUE for all sets.

Delta lognormal analyses (Lo et~al.~1992, Maunder and Punt 2004) used a binomial distribution for the probability w of catch rate being zero and a probability distribution f(y), where y was log(catch/hooks set), for non-zero (positive) catch rates. The index estimated for each year-quarter was the product of the year effects for the two model components. $(1-w).E(y|y\neq 0)$.

$$Pr(Y=y) = \begin{cases} w, & y=0\\ (1-w)f(y) & otherwise \end{cases}$$

 $g(w) = (\mathit{CPUE} = 0)$ $\mathit{covariates} + \varepsilon$, where g is the logistic function.

$$f(y)$$
=CPUE covariates + ϵ

Negative binomial analyses used the function glm.nb from the MASS package (Venables and Ripley 2002) in R, using the default options. The response variable was catch in numbers.

In each case the covariates included year-quarter, (yrqtr), 5° cell, (latlong5), and cluster (cl) fitted as categorical variables, and a cubic spline function h with 10 degrees of freedom applied to the continuous variable hooks. Some analyses included the vessel identifier vessid as a categorical variable. Some analyses included a cubic spline φ applied to the continuous variable hooks between floats (hbf).

Data in all models except the binomial model were 'area-weighted', with the weights of the sets adjusted so that the total weight per year-quarter in each 5° square would sum to 1. This method was based on the approach identified using simulation by Punsly (1987) and Campbell (2004), that for set j in area i and year-quarter t, the weighting

function that gave the least average bias was: $w_{ijt} = \frac{\log |h_{ijt} + 1|}{\sum_{i=1}^{n} \log |h_{ijt} + 1|} \text{ . Given the}$

relatively low variation in number of hooks between sets in a stratum, we simplified this

to
$$w_{ijt} = \frac{h_{ijt}}{\sum_{i=1}^{n} h_{ijt}}$$
.

For the lognormal constant and positive lognormal GLMs, model fits were examined by plotting the residual densities and using Q-Q plots.

14

3.3.2. Models and datasets

In order to explore alternative approaches to the analysis, the four approaches below were applied for each of the tropical tuna species. Albacore was modelled with the second approach only.

- 1. Data omitted low-target clusters. Model included HBF but not cluster.
- 2. Data omitted low-target clusters. Model included cluster but not HBF.
- 3. Data omitted low-target clusters. Model included neither HBF nor cluster.
- 4. All data included. Model included HBF but not cluster.

3.3.3. Data periods

Vessel identity information was only available from 1979, so could not be applied uniformly across all years. The discontinuity in 1979 could be addressed in several different ways. We therefore analysed the data in several ways so as to provide the assessment scientists with appropriate data. For each of the approaches above, four analyses were carried out (Table 1).

TABLE 1: ANALYSIS APPROACHES FOR ADDRESSING THE DISCONTINUITY IN AVAILABILITY OF VESSEL IDENTITY.

Analysis	Years	Vessel effects
1	1952-1979	No
2	1979-2015	Yes
3	1952-2015	No
4	1952-2015	Yes

It is possible to standardize the time series with vessel effects by assigning an identical dummy value to all vessels without vessel identity information. This was done for analysis 3). However using a dummy value introduces several problems. First, not all vessels begin to report their callsign at once in 1979, and those that do are self-selected and not randomly selected from the vessel population. Therefore it cannot be assumed that fishing power remains constant after 1979 for the dummy vessel id, so the transition in 1979 may introduce a discontinuity into the time series. The discontinuity can be limited in scope by restricting the overlap between dummy and real vessel IDs to one year – 1979 – and removing sets with missing vessel IDs after this time. Secondly, residuals may be more variable before 1979, without a true vessel ID in the model, which can introduce bias into the standardization.

One approach for addressing the discontinuity in analysis 3) is to adjust the time period 1952-1978 so that the relative averages in 1978 and 1979 are the same. as they are in analysis 4), without vessel effects. However we considered that a better approach may be to estimate two time series 1952-1979 without vessel effects, and a second time series 1979-2015 with vessel effects (omitting all sets without vessel IDs). These are analyses 1) and 2) above. Subsequently the analyst can use them as desired, for example concatenating them after adjusting the averages so that the estimates for 1979 are the same.

3.3.4. Covariate effects

The effects of covariates were examined by plotting the predicted effects, with 95% confidence limits, of each parameter at observed values of the explanatory variables. Spatial effects with 95% confidence intervals were plotted by latitude. The cumulative vessel effects through time were examined by plotting each vessel's effect at every time that vessel made a set. An average vessel effect over time was examined by calculating the mean of the vessel effects for all sets made by the fleet during each time period, and

this was also plotted. There was insufficient space to include all plots in the report, but these are available on request.

Changes in catchability through time were investigated by fitting to the operational data both with and without a term for individual vessel. The two models were designated respectively the 'base model' and the 'vessel-effects model'. Abundance indices were calculated for each model, and normalized to average 1.

For all model comparisons, the indices estimated for each year-quarter were compared by dividing the base model by the vessel effects model, plotting the time series of ratios, and fitting a log-linear regression. The slope of the regression represented the average annual compounding rate of change in fishing power attributable to changes in the vessel identities; i.e. the introduction of new vessels and retirement of old vessels. Gradients are shown on the figures, together with confidence intervals.

3.3.5. Indices of abundance

Indices of abundance were obtained by applying the R function predict.glm to model objects. Binomial time effects were obtained by generating time effects from the glm and adjusting them so that their mean was the proportion of positive sets across the whole dataset. The main aim with this approach is to obtain a CPUE that varies appropriately, since variability for a binomial is greater when the mean is at 0.5 than at 0.02 or 0.98, and the multiplicative effect of the variability is greater when the mean is lower. The outcomes were normalised and reported as relative CPUE with mean of 1.

Uncertainty estimates were provided by applying the R function predict.glm with type = "terms" and se.fit=TRUE, and taking the standard error of the year-quarter effect. For the delta lognormal models we used only the uncertainty in the positive component. Uncertainty estimates from standardizing commercial logbook data are in general biased low and often ignored by assessment scientists, since they assume independence and ignore autocorrelation associated with (for example) consecutive sets by the same vessels in the same areas. There may be a very large mismatch between the observation error in CPUE indices and the process error in the indices that is estimated in the assessment. This is particularly true for distant water longline CPUE, where very large sample sizes generate small observation errors.

Residual distributions and Q-Q plots were produced for all but the binomial analyses. For the lognormal positive analyses that included cluster in the model, median residuals were plotted by cluster. For all lognormal positive analyses, residuals by year-quarter were plotted by flag; median residuals by year-quarter were plotted by flag; and median residuals by 5° cell were mapped onto a contour plot for each flag.

We compared the indices with the area-specific Japanese bigeye indices from 2013 (Matsumoto *et al.* 2013) and yellowfin indices from 2015 (Ochi *et al.* 2015). The 2013 bigeye indices provided only a whole-of-area index in the southern temperate area, so this was compared with both the east and west joint indices. For each comparison, each dataset was first normalised by dividing through by its mean for 1980-2000, and the datasets plotted on the same axes. Secondly, the joint indices were divided by the matching year-quarter values from the Japanese indices, and these ratios were plotted to show the relative trends of the two time series.

4. Results and Discussion

4.1. Cluster analysis

The aim of the cluster analysis was first to identify separate fishing strategies in the data for each species, regional structure, fleet, and region, and so to better understand the fishing practices; and second to assign each unit of fishing effort to a particular fishing strategy, so that the clusters could be used in standardization.

We clustered the data using helust and kmeans methods for each region and fleet. Due to space limitations we report clustering results for regional structure A3 only. Results for regional structures A2 and A5 are similar.

The hclust trip and untransformed kmeans set methods separated Japanese, Korean and Taiwanese effort into 3-5 fishing strategies in each region (Error: Reference source not found, Figures Figure 9-Figure 12). Please note that the order of the clusters in the dendrograms does not match the cluster numbers.

Species compositions were plotted by cluster for each region and fleet, as were the relative distributions of covariates (Figures Figure 13–Figure 20).

In region 1 for all three fleets, we included a cluster characterized by a high proportion of albacore and low to moderate yellowfin, with low levels of other species (Figure 13). The main Japanese cluster derived largely from the early period (Figure 14). All three fleets covered most of the spatial domain east of Madagascar and south of about 15° S (Figure 21). For the Japanese fleet, a second cluster with moderate proportions of albacore and bigeye and relatively high yellowfin was included, mostly from northern areas.

In region 2, only one cluster was selected from each fleet (Figure 15), which for Japan was high in albacore and moderate in bigeye and yellowfin. The Korean cluster included moderate levels of albacore and yellowfin, but slightly more bigeye. The Taiwanese cluster was dominated by albacore. Clusters for all fleets were more concentrated in the earlier parts of the time series (Figure 16). The Japanese and Taiwanese clusters were south of about 15 S, as in region 1, but the Korean cluster was further north (Figure 22), probably because there was very little Korean effort further south in region 2.

In region 3, one cluster was selected for the Japanese and Korean fleets, but two clusters for the Taiwanese fleet (Figure 17). The Japanese cluster had good coverage across most of the time series, as did the Taiwanese cluster, whereas the Korean cluster was less evenly distributed (Figure 18). The spatial coverage of the Japanese and Taiwanese clusters was also broad (Figure 23). There were some striking patterns of changing species composition in the Japanese time series at 30S and 35S, which were not seen in any other fleet or region. These may warrant further investigation.

In region 4, a single cluster was selected for Japan and 2 clusters each for the Korean and Taiwanese fleets (Figure 19). The Japanese cluster was based mostly on albacore, with small proportions of bigeye and southern bluefin tuna. The cluster had good temporal coverage, as did the Taiwanese clusters (Figure 20). For Japan and Korea the clusters were focused north of about 37 S, with more southern effort in southern bluefin tuna clusters. For Taiwan the albacore clusters included most of the effort in region 4, which for the Taiwanese fleet went only as far south as 40 S (Figure 24).

4.2. CPUE indices

We estimated indices for all regions of regional structure A3 (Tables Error: Reference source not found-Error: Reference source not found, Figures Figure 25-Figure 28), and for the single region of regional structure A5 (Tables Error: Reference source not found-Error: Reference source not found, Figure 29). A limited range of diagnostics indicated reasonably normal distributions of residuals (Figures Figure 30-Figure 32).

Indices in the northern areas were characterized by steep or very steep declines in standardized CPUE prior to 1975, particularly in region 1. After 1980 the region 1 CPUE increased until 1995 and then decreased. For the north-eastern region 2, data were sparse after about 1990, with no clear signal in the estimates. Fish sizes are larger in northern areas, so catch rates here may reflect abundance trends of older fish.

The southwestern area region 3 also showed a steep decline until about 1970, followed by more stable catch rates from 1970–2010. There were indications of a drop in catch rates after 1985, followed by recovery of catch rates after the mid-1990s, and further increase beginning in about 2005. The south-eastern area region 4 was the only region in which no steep decline in catch rates was observed prior to 1970. After 1980 the index declines somewhat, followed by an increase beginning in about 2005.

The CPUE trends estimated here address a number of concerns about indices used in previous assessments. Models are run separately for different areas, which addresses concerns about differing parameter estimates and uncertainty distributions in different areas (Chang et al. 2011). The models use 5° cell area effects, as recommended by the 2013 IOTC CPUE workshop (Anon 2013) to account for changes in effort distribution, and adjusts statistical weights to allow for changing effort concentration (Punsly 1987, Campbell 2004). The models include vessel effects, which accounts for some effects of changing fishing power and targeting within the fleet (Hoyle and Okamoto 2011). It also uses cluster analysis based on species composition in order to identify target change, and to separate out effort using different fishing strategies (He et al. 1997).

However, concerns remain about the indices estimated in this study. The declines in the indices before 1970 are too steep to represent abundance change, given the relatively low catches taken during this period. Similar declines are seen in albacore indices in other oceans (e.g. Hampton *et al.* 2005), even after clustering (Bigelow and Hoyle 2012). Factors causing the declines are unclear, but in addition to unresolved effects of target change may include changing catchability due to removal of the most vulnerable individuals (Gulland 1974, Maunder *et al.* 2006).

The indices also show increasing CPUE from 2005, during a period when Japanese effort began targeting albacore tuna. There is a strong suggestion that cluster analysis may not have fully accounted for target change, and that indices may be biased upward during this period. Further investigation is needed to explore this issue, which should include investigating residuals by fleet, the effects of piracy on fleet distribution, exploring the timing of the changes seasonally, and possibly relationship with target switching by the southern bluefin tuna fleet after quotas have been met.

5. Acknowledgments

Thanks to the International Seafood Sustainability Foundation (ISSF) and the Indian Ocean Tuna Commission (IOTC) for funding this work. We are grateful to the IOTC for facilitating. Special thanks to James Geehan of IOTC for facilitating and rapporteuring the

final meeting. Thanks to the Japanese,. Taiwanese, and Korean Governments and fishing industries for allowing their data to be used in these analyses. Thanks to the Taiwanese Overseas Fisheries Development Council, Japanese Institute for Far Seas Fisheries at Shimizu, and the Shanghai Ocean University for providing their facilities and support. Thanks to Ren-Fen Wu and Lisa Chang for their thoughtful contributions and organizational support.

operation longitude	Integer	170-172	NO	YES	YES	
departure date from port	Integer	176-183	YES	YES	YES	
starting date to operation	Integer	185-192	NO	YES	YES	
stop date to operation	Integer	194-201	NO	YES	YES	
arrival date at port	Integer	203-210	YES	YES	YES	

Table 5: Tonnage as indicated by first digit of TW callsign.

First digit	Tonnage
1	>= 5 and < 10 tonnes
2	>= 10 and < 20 tonnes
3	>= 20 and < 50 tonnes
4	>= 50 and < 100 tonnes
5	>= 100 and < 200 tonnes
6	>= 200 and < 500 tonnes
7	>= 500 and < 1,000 tonnes
8	>= 1,000 tonnes

Table 6: Codes in the Remarks field of the TW dataset, indicating outliers.

Dates	Code	Outliers
2007-2011	G1	extremely high BET catch
	G4	extremely high ALB
	G6	extremely high YFT catch
	G8	extremely high SWO;
	SF	for a given year and vessel, record only single species catch for 3 successive months
2012-2013	G1	extremely high ALB catch
	G2	extremely high BET
	G3	extremely high YFT catch
	G7	extremely high SWO
	GH	abnormal total no. of hooks per set
	GL	more than one anomaly
	SF	for a given year and vessel, only record single species catch for 3 successive months

2007-2011:

1.G1:extremely high BET catch (> 5 tons per set or outliers in the distribution of bet catch number per set); G4: extremely high ALB;

G6: extremely high YFT catch; G8: extremely high SWO;

SF: for a given year and a given vessel, record only single species catch for three successive months.

2012-2014:

G1: extremely high ALB catch (Based on definition of IOTC BET regions, for a given year and a given region, average catch numbers per set for a given vessel. Then use the IQR Rule*. Remark all sets by the vessel which reported the outlier for the given year and region); G2: extremely high BET;

G3: extremely high YFT catch; G7: extremely high SWO;

GH: abnormal total no. of hooks per set;

GL: if there are more than one anomaly.

SF: for a given year and a given vessel, only record single species catch for three successive months.

Criteria for outliers

(> 5 tons per set or outliers in the distribution of bet catch number per set)

*IQR Rule for Outliers

- 1. Arrange average catch numbers per set for all vessels in order.
- 2. Calculate first quartile (Q1), third quartile (Q3) and the interquartile range (IQR=Q3-Q1).
- 3. Compute Q1-1.5 x IQR and Compute Q3+1.5 x IQR. Anything outside this range is an outlier.

Table 7a: Taiwanese data sample sizes by variable.

Year	No. of ops	Cruise start date	Cruise end date	Op start date	Op end date

8. Figures

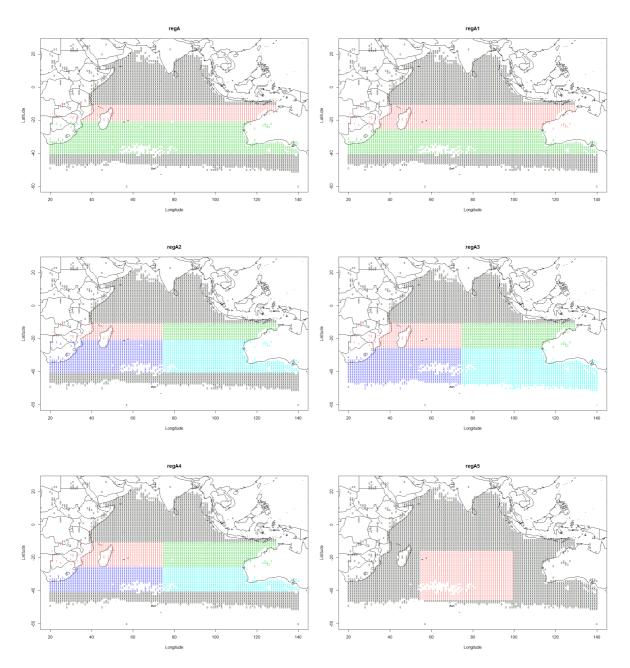

Figure 1: Maps of the alternative regional structures used to estimate albacore CPUE indices.

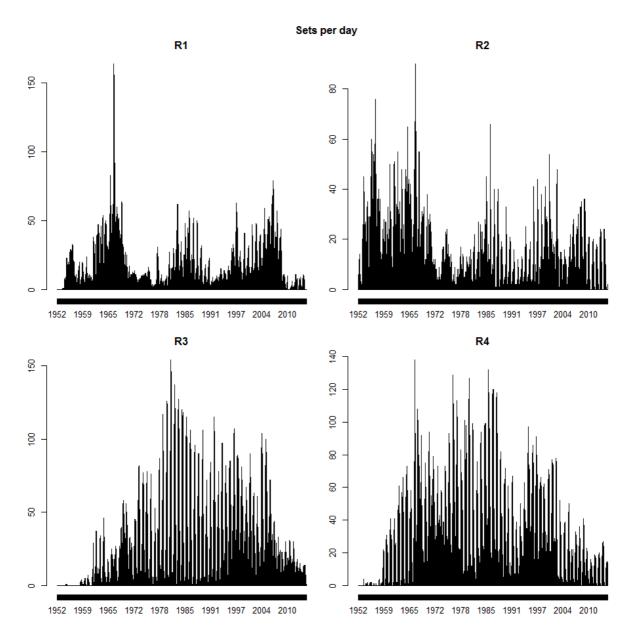

Figure 2: Sets per day by region for the Japanese fleet in regional structure A2.

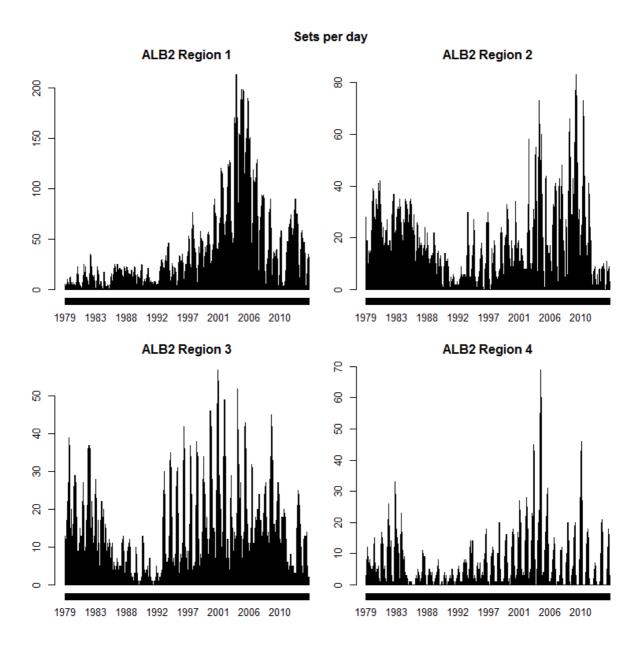

Figure 3: Sets per day by region for the Taiwanese fleet in regional structure A2.

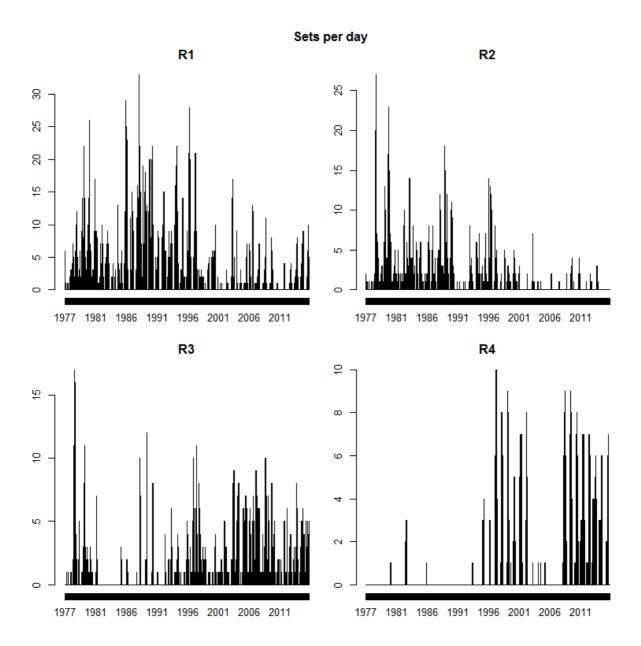

Figure 4: Sets per day by region for the Korean fleet in regional structure A2.

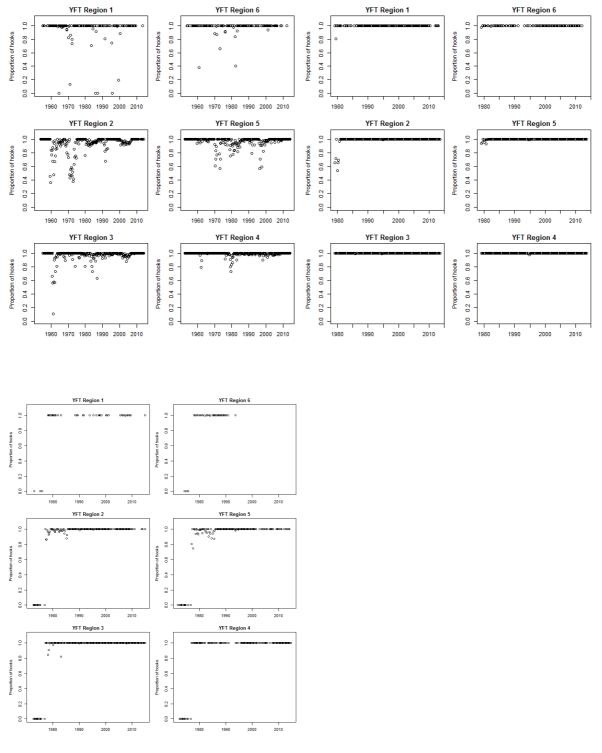

Figure 5: Proportions of sets retained after data cleaning for analyses in this paper, by region and yrqtr, for Japanese (top left), Taiwanese (top right), and Korean (bottom left) data.

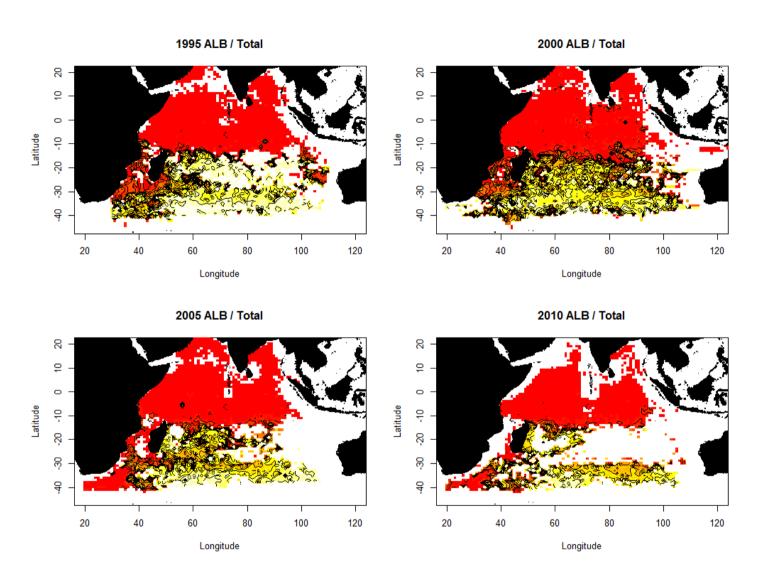

Figure 6: Proportions of Taiwanese catch in number reported as albacore, by 5 year period, mapped by 1° square. More yellow indicates a higher percentage of albacore. Contour lines occur at 5% intervals.

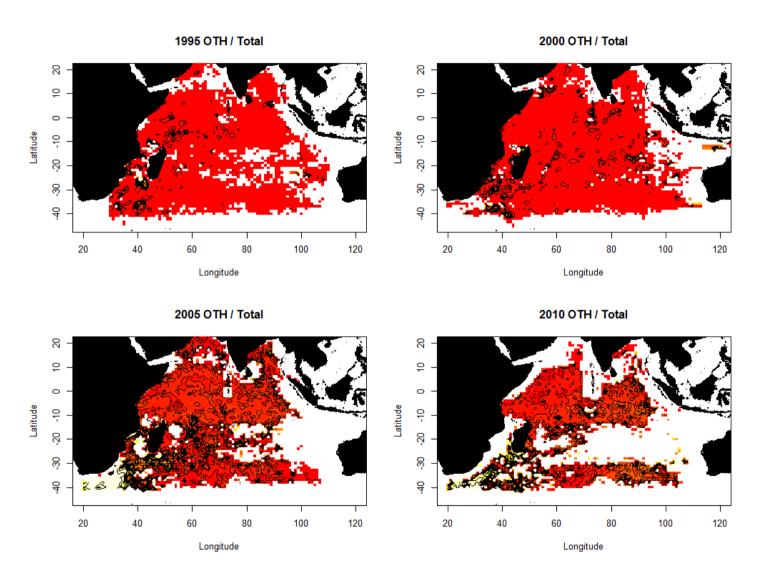

Figure 7: Proportions of Taiwanese catch in number reported as 'other' species, by 5 year period, mapped by 1° square. More yellow indicates a higher percentage of 'other' species. Contour lines occur at 5% intervals.

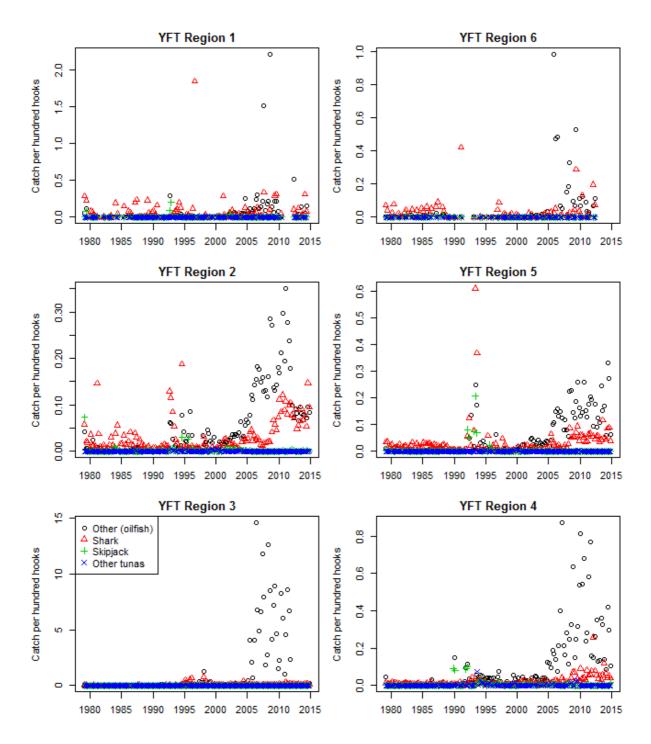

Figure 8: Taiwanese catch rates per hundred hooks of oilfish, sharks, skipjack, and other tunas, by region and year-qtr.

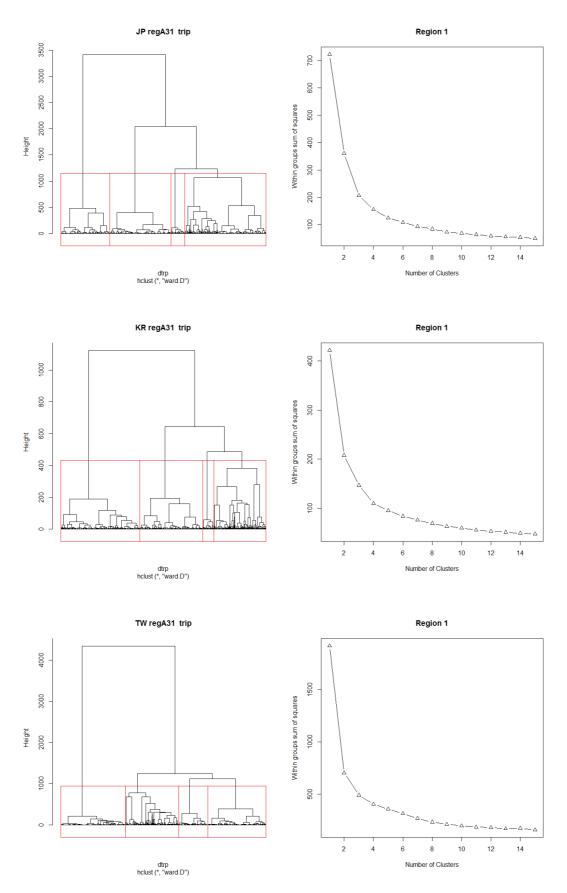

Figure 9: Plots showing analyses to estimate the number of distinct classes of species composition in A3 region 1 for Japanese, Korean, and Taiwanese effort. These are based on a hierarchical Ward

clustering analysis of trip-level data (left); and within-group sums of squares from kmeans analyses with a range of numbers of clusters (right).

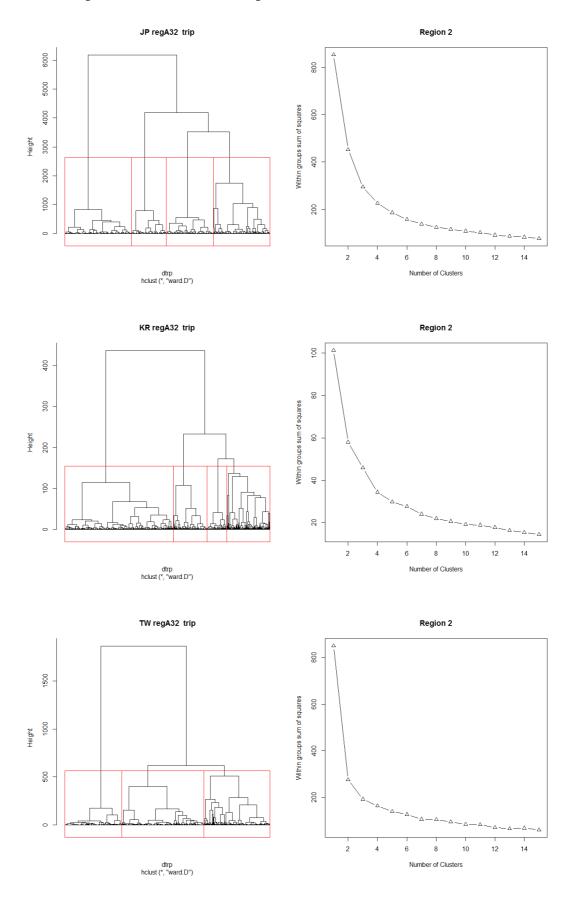

Figure 10: Plots showing analyses to estimate the number of distinct classes of species composition in A3 region 2 for Japanese, Korean, and Taiwanese effort. These are based on a hierarchical Ward clustering analysis of trip-level data (left); and within-group sums of squares from kmeans analyses with a range of numbers of clusters (right).

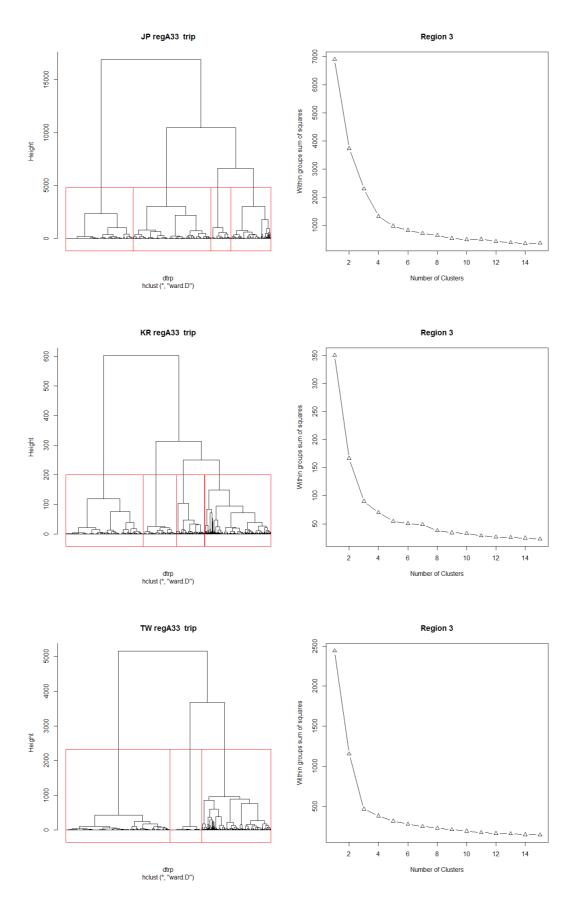

Figure 11: Plots showing analyses to estimate the number of distinct classes of species composition in A3 region 3 for Japanese, Korean, and Taiwanese effort. These are based on a

hierarchical Ward clustering analysis of trip-level data (left); and within-group sums of squares from kmeans analyses with a range of numbers of clusters (right).

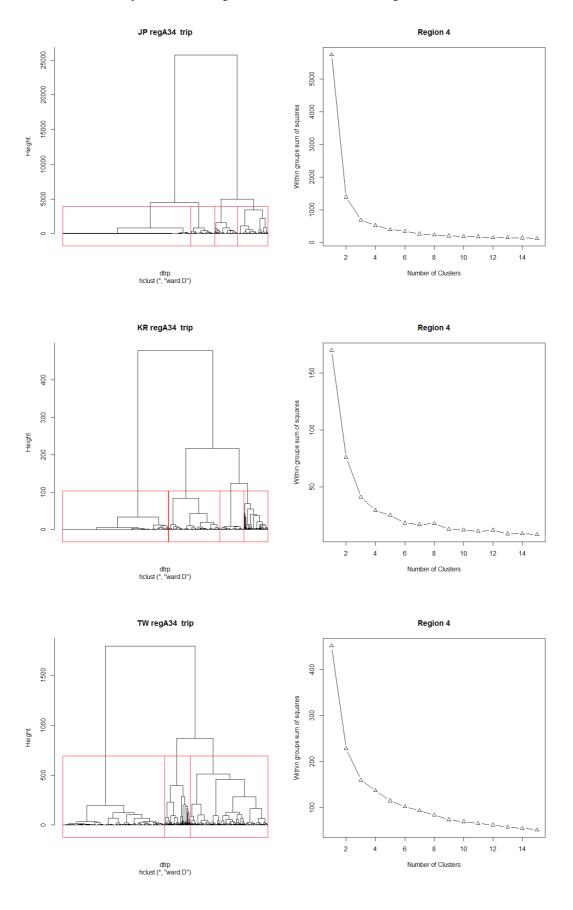

Figure 12: Plots showing analyses to estimate the number of distinct classes of species composition in A3 region 4 for Japanese, Korean, and Taiwanese effort. These are based on a hierarchical Ward clustering analysis of trip-level data (left); and within-group sums of squares from kmeans analyses with a range of numbers of clusters (right).

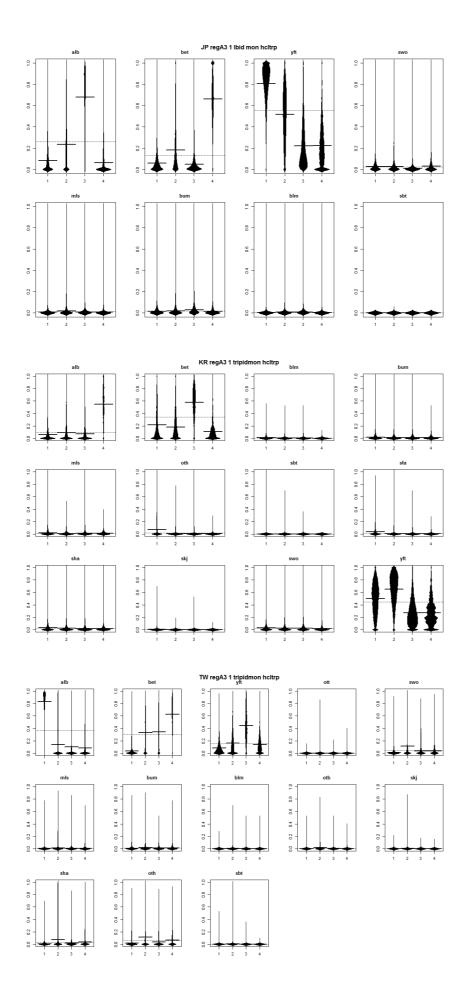

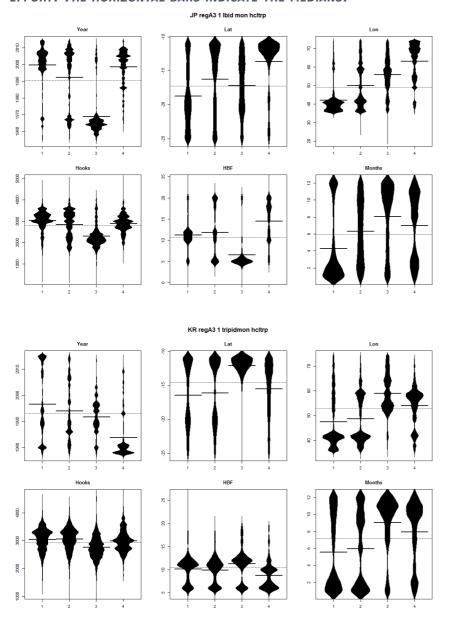

FIGURE 13: BEANPLOTS FOR REGION 1 OF REGIONAL STRUCTURE A3 SHOWING SPECIES COMPOSITION BY CLUSTER FOR JAPANESE (TOP), KOREAN (MIDDLE) AND TAIWANESE (BOTTOM) EFFORT. THE HORIZONTAL BARS INDICATE THE MEDIANS.

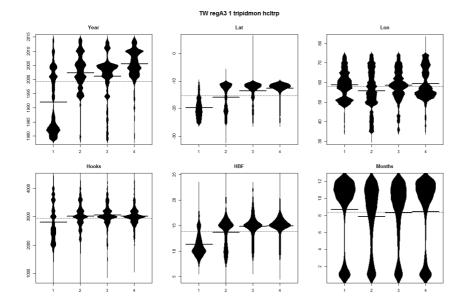

FIGURE 14: BEANPLOTS FOR REGION 1 OF REGIONAL STRUCTURE A3 SHOWING NUMBER OF SETS VERSUS COVARIATE BY CLUSTER FOR JAPANESE (TOP), KOREAN (MIDDLE) AND TAIWANESE (BOTTOM) EFFORT. THE HORIZONTAL BARS INDICATE THE MEDIANS.

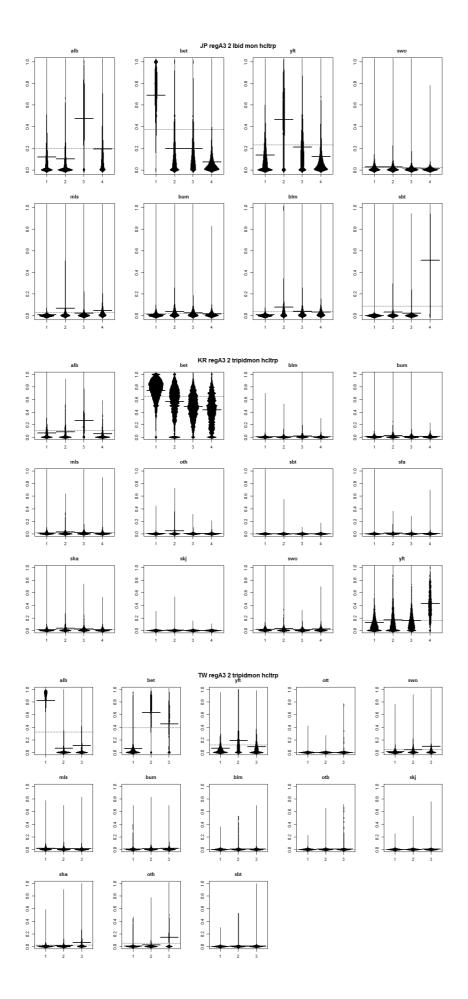

Figure 15: Beanplots for region 2 of regional structure A3 showing species composition by cluster for Japanese (top), Korean (middle) and Taiwanese (bottom) effort. The horizontal bars indicate the medians.

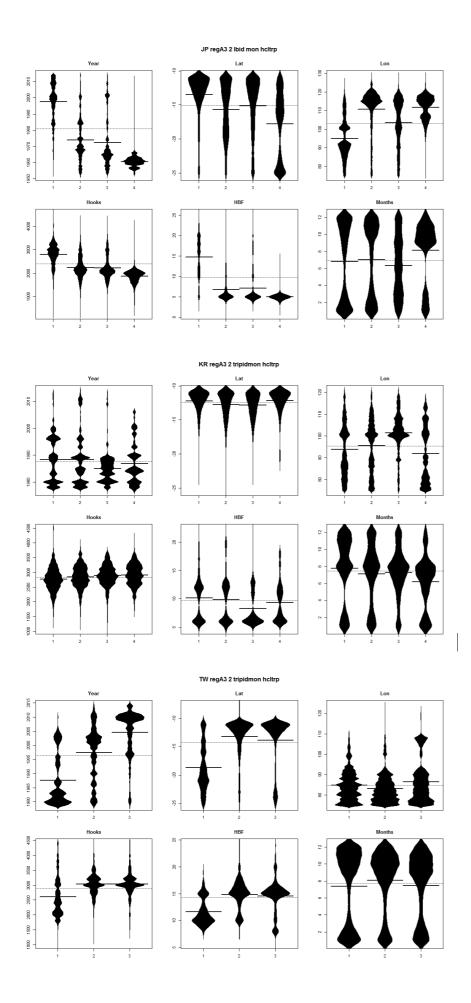

FIGURE 16: BEANPLOTS FOR REGION 2 OF REGIONAL STRUCTURE A3 SHOWING NUMBER OF SETS VERSUS COVARIATE BY CLUSTER FOR JAPANESE (TOP), KOREAN (MIDDLE) AND TAIWANESE (BOTTOM) EFFORT. THE HORIZONTAL BARS INDICATE THE MEDIANS.

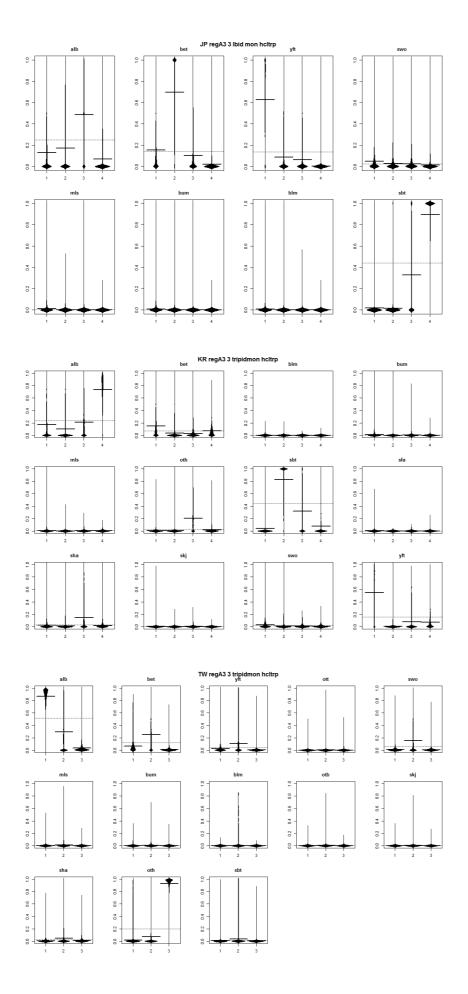

Figure 17: Beanplots for region 3 of regional structure A3 showing species composition by cluster for Japanese (top), Korean (middle) and Taiwanese (bottom) effort. The horizontal bars indicate the medians.

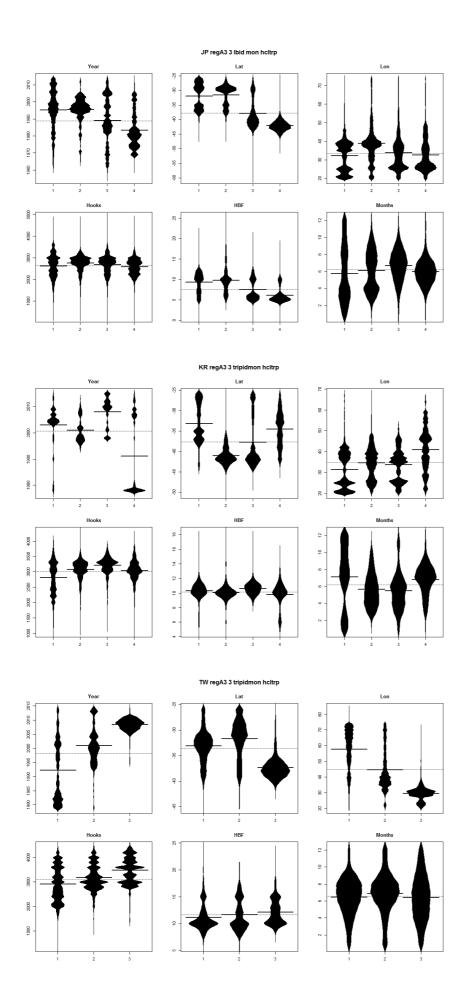

FIGURE 18: BEANPLOTS FOR REGION 3 OF REGIONAL STRUCTURE A3 SHOWING NUMBER OF SETS VERSUS COVARIATE BY CLUSTER FOR JAPANESE (TOP), KOREAN (MIDDLE) AND TAIWANESE (BOTTOM) EFFORT. THE HORIZONTAL BARS INDICATE THE MEDIANS.

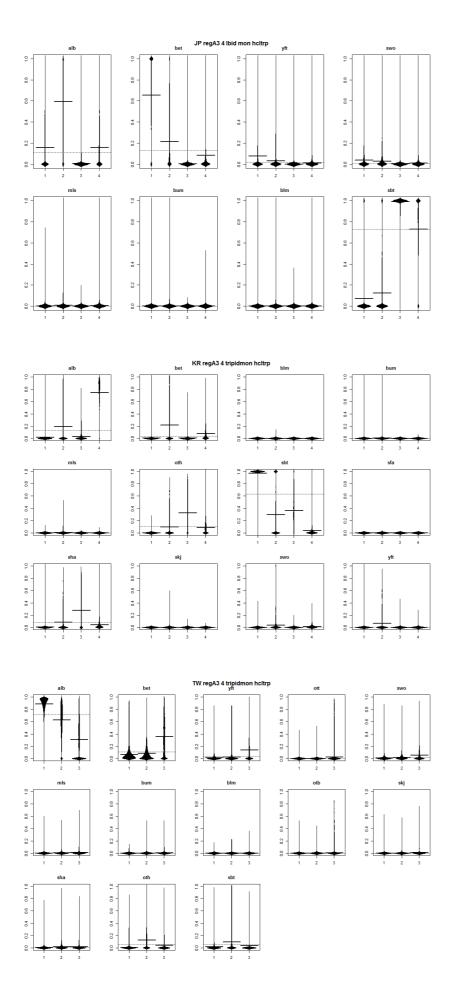

Figure 19: Beanplots for region 4 of regional structure A3 showing species composition by cluster for Japanese (top), Korean (middle) and Taiwanese (bottom) effort. The horizontal bars indicate the medians.

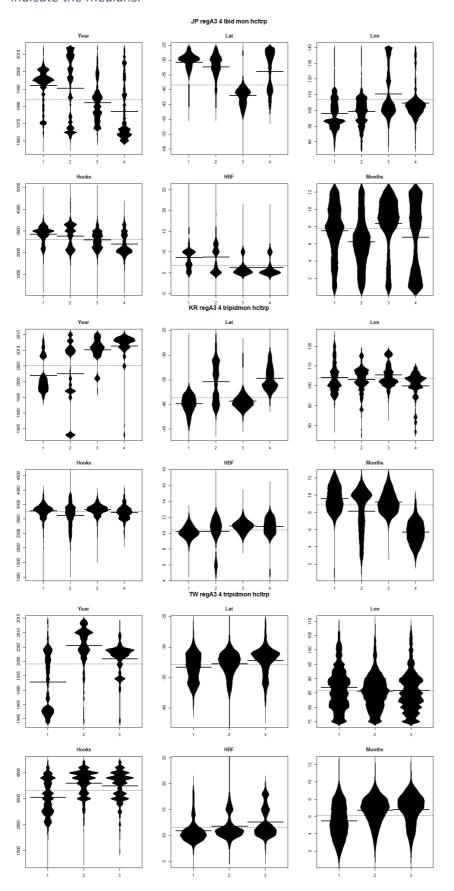

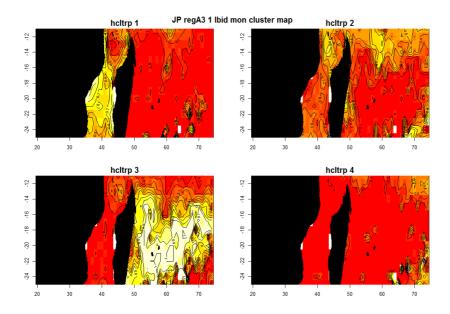

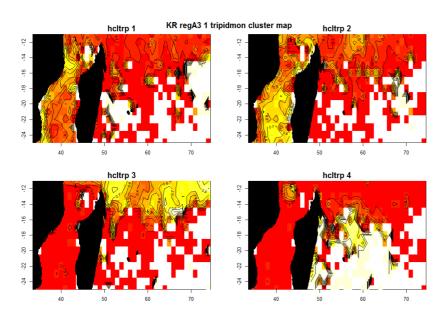

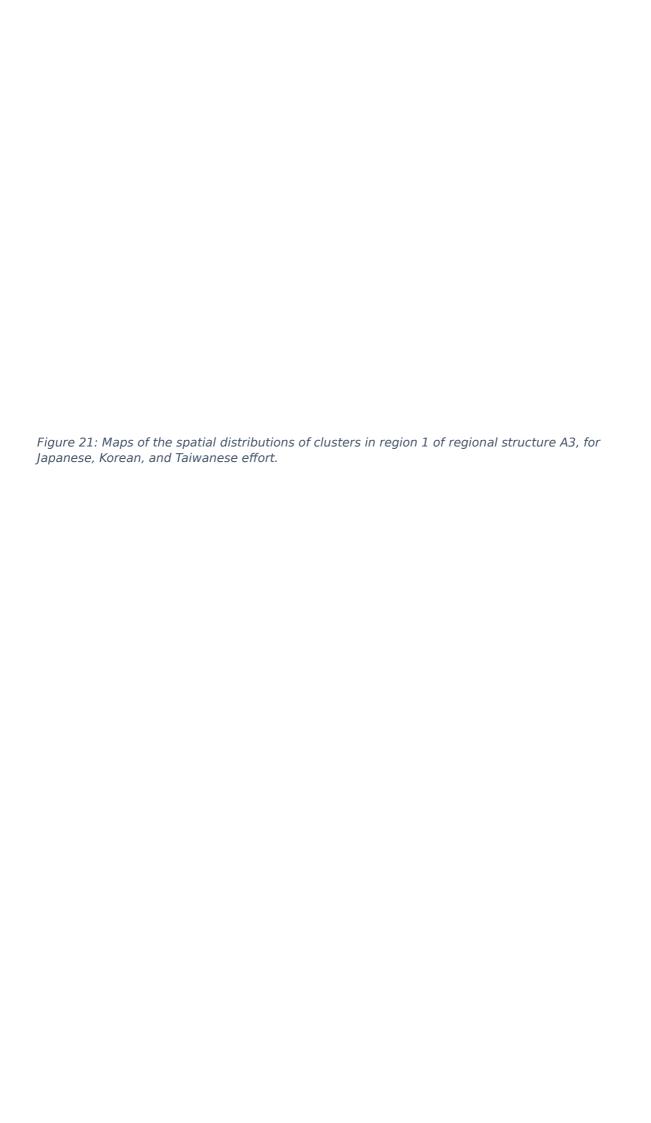

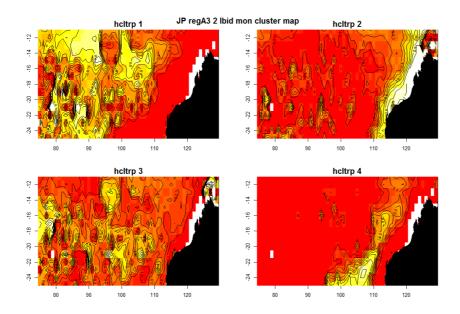

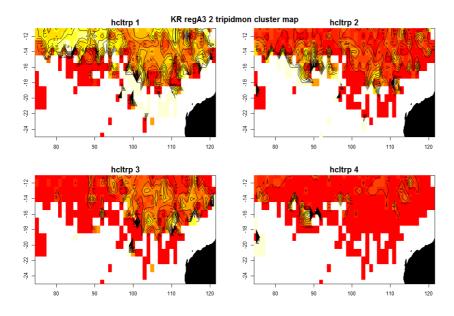

FIGURE 20: BEANPLOTS FOR REGION 4 OF REGIONAL STRUCTURE A3 SHOWING NUMBER OF SETS VERSUS COVARIATE BY CLUSTER (RIGHT) FOR JAPANESE (TOP), KOREAN (MIDDLE) AND TAIWANESE (BOTTOM) EFFORT. THE HORIZONTAL BARS INDICATE THE MEDIANS.

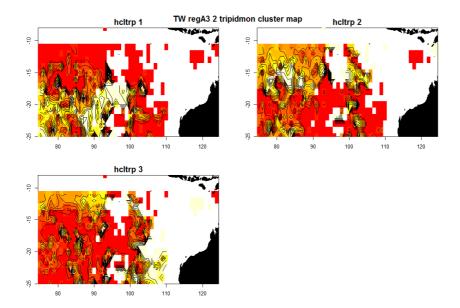

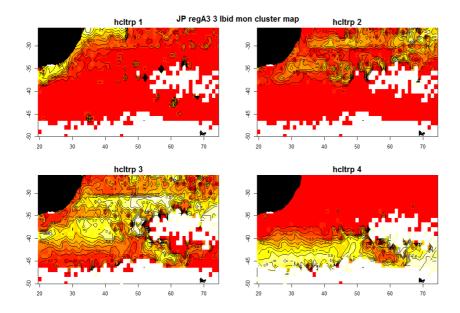

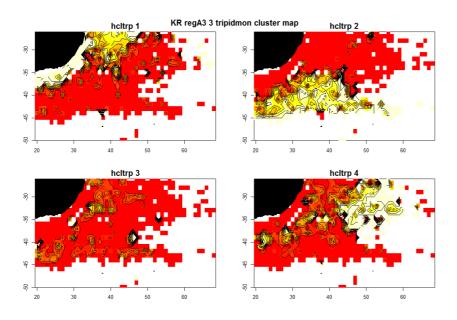

Figure 22: Maps of the spatial distributions of clusters in region 2 of regional structure A3, for Japanese, Korean, and Taiwanese effort.

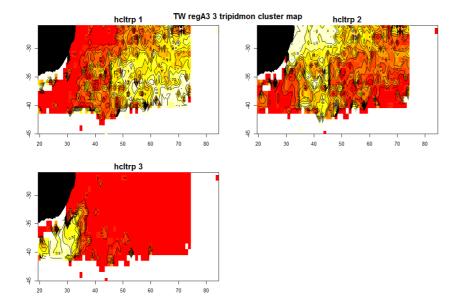

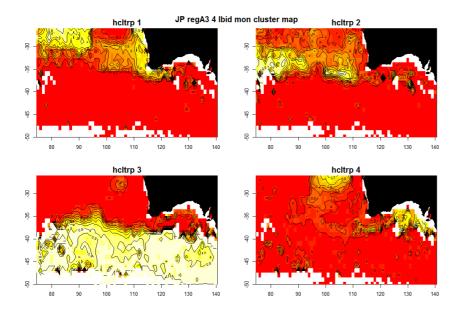

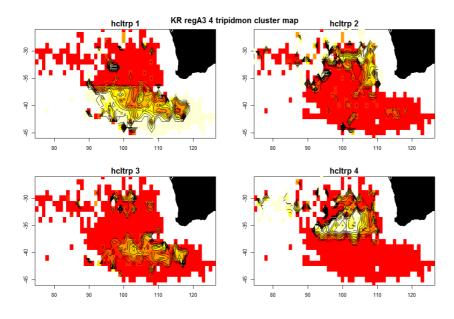

Figure 23: Maps of the spatial distributions of clusters in region 3 of regional structure A3, for Japanese, Korean, and Taiwanese effort.

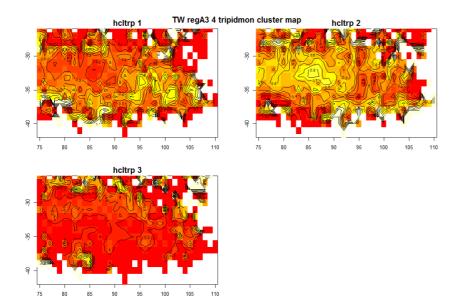

Figure 24: Maps of the spatial distributions of clusters in region 4 of regional structure A3, for Japanese, Korean, and Taiwanese effort.

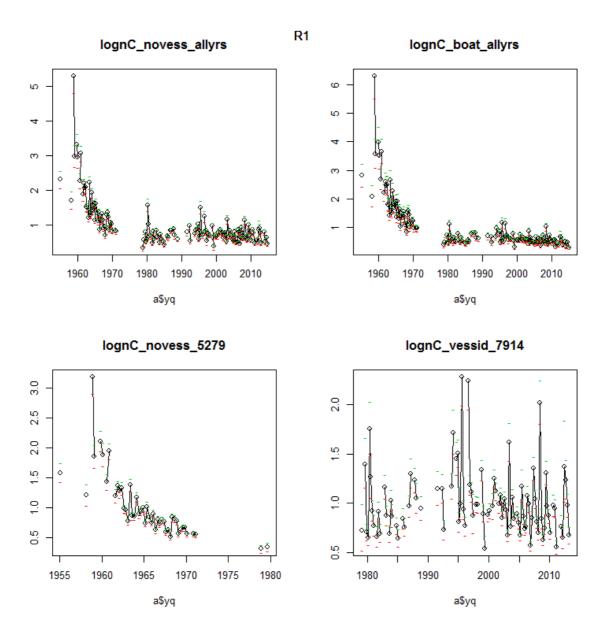

Figure 25: Estimated CPUE series for region 1 of the A3 regional structure, including time series for all years (top) both with (right) and without (left) vessel effects, and time series for 1952-79 without vessel effects, and 1979-2014 with vessel effects.

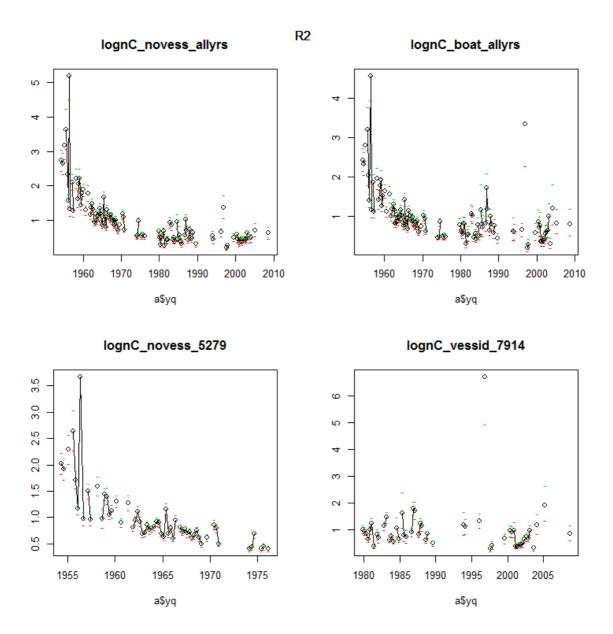

Figure 26: Estimated CPUE series for region 2 of the A3 regional structure, including time series for all years (top) both with (right) and without (left) vessel effects, and time series for 1952-79 without vessel effects, and 1979-2014 with vessel effects.

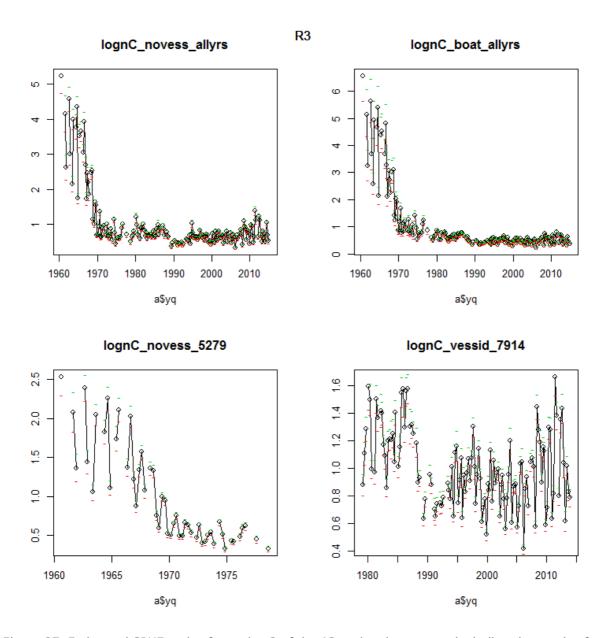

Figure 27: Estimated CPUE series for region 3 of the A3 regional structure, including time series for all years (top) both with (right) and without (left) vessel effects, and time series for 1952-79 without vessel effects, and 1979-2014 with vessel effects.

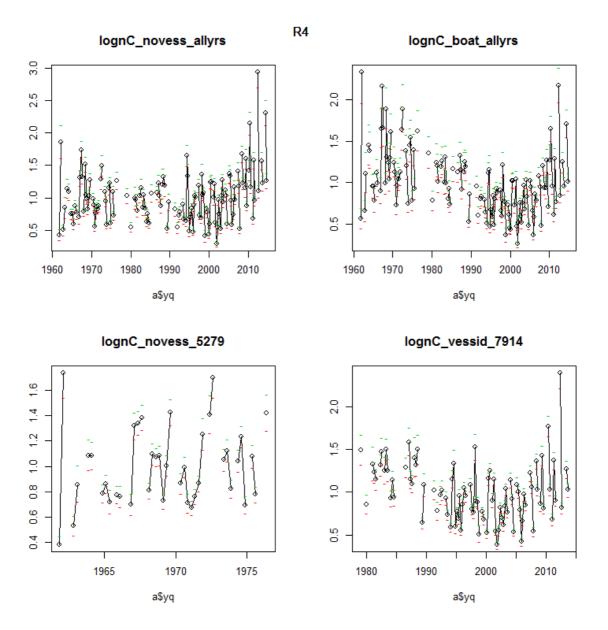

Figure 28: Estimated CPUE series for region 4 of the A3 regional structure, including time series for all years (top) both with (right) and without (left) vessel effects, and time series for 1952-79 without vessel effects, and 1979-2014 with vessel effects.

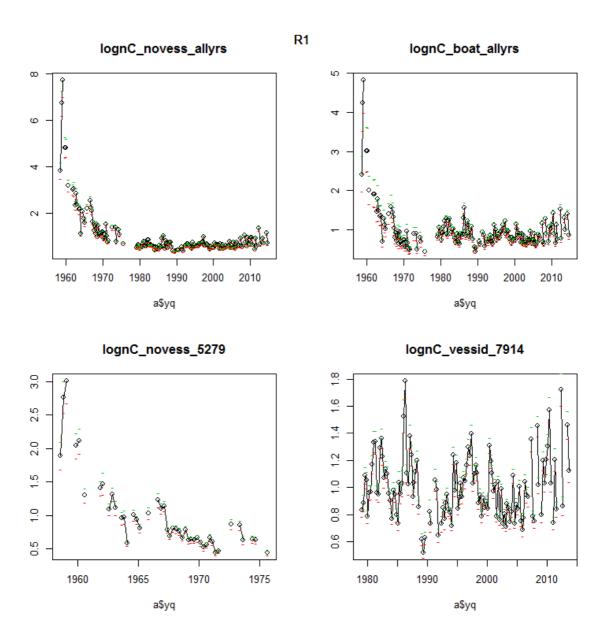

Figure 29: Estimated CPUE series for the single region of the A5 regional structure, including time series for all years (top) both with (right) and without (left) vessel effects, and time series for 1952-79 without vessel effects, and 1979-2014 with vessel effects.

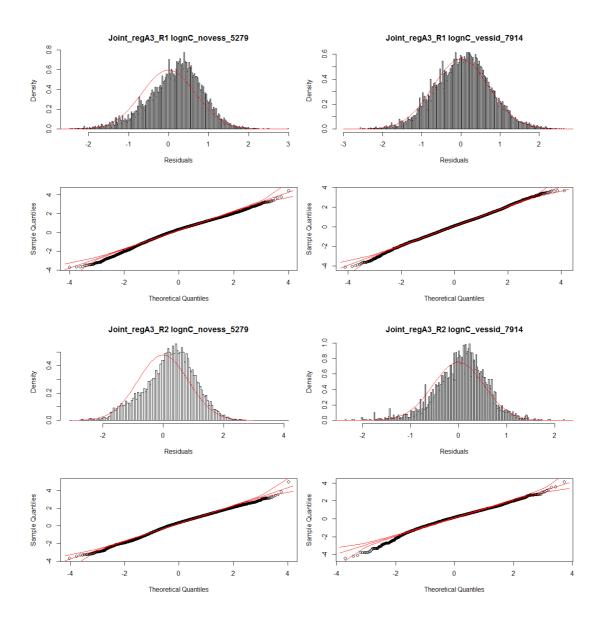

Figure 30: Diagnostics plots for lognormal constant models in regions 1 and 2 of the A3 regional structure, for 1952-79 without vessel effects (left) and for 1979-2014 with vessel effects (right).

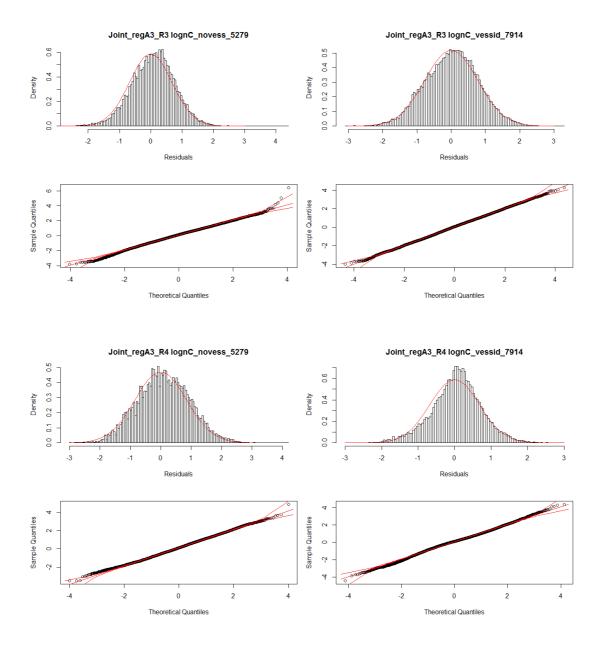

Figure 31: Diagnostics plots for lognormal constant models in regions 3 and 4 of the A3 regional structure, for 1952-79 without vessel effects (left) and for 1979-2014 with vessel effects (right).

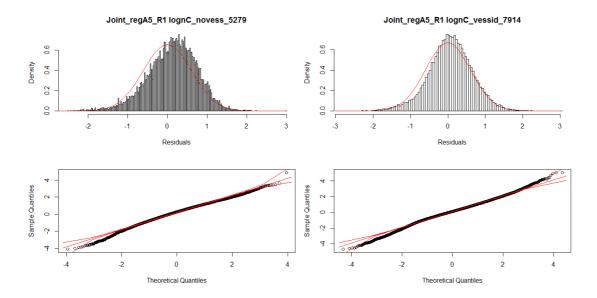

Figure 32: Diagnostics plots for lognormal constant models in the single region of the A5 regional structure, for1952-79 without vessel effects (left) and for 1979-2014 with vessel effects (right).
